ABSTRACT

This thesis describes the design and employment of a general transportation and distribution simulation toolbox and an extension to that toolbox used to model the instream offload of a Marine Expeditionary Unit (MEU) Slice of a Maritime Prepositioning Force (MPF). The Simulated Mobility Modeling and Analysis Toolbox (SMMAT) is a toolbox of object oriented modules written in MODSIM II® by faculty and students, including the author, of the Naval Postgraduate School for transportation and distribution modeling. The MEU Slice offload model is built as an extension to SMMAT, with itself being easily extendible to model other aspects of MPF operations. The objective of this thesis was twofold, (1) to build SMMAT and demonstrate its feasibility as a toolbox, and (2) to determine which of four asset distribution setups ashore, at varying levels of equipment reliability, will allow for the fastest offload and throughput of the MEU slice. This thesis successfully demonstrated SMMAT's usefulness as a transportation and distribution simulation toolbox, and the MEU Slice study indicates that no one distribution setup ashore is statistically faster than any other one.

EXECUTIVE SUMMARY

A. BACKGROUND

Following the Iranian hostage crisis of 1979, the Department of Defense began exploring the concept of using prepositioned equipment to aid in contingency rapid response. The Marine Corps' long term answer to this initiative was the formation of today's Maritime Prepositioning Force (MPF). The MPF is the marriage of a Maritime Prepositioning Ship (MPS) Squadron (MPSRON) and a Marine Expeditionary Brigade (MEB). Three MPSRON's are afloat independently throughout the world awaiting the call to join with a Marine Air Ground Task Force (MAGTF) for rapid deployment in case of crisis prevention and intervention.

When the MPS's were first loaded (1984 - 1986), all ships were evenly loaded with equipment and supplies to reduce the impact of one or more ships being lost or unable to participate in an operation. This spreadloading forced the use of the entire MPSRON or none of it. The MPSRON could not effectively offload just the equipment and supplies needed to support a smaller MAGTF. In the mid to late 1980's, the following force modules were developed, and later implemented, for a more flexible employment of the MPF.

- the MEU Slice - all equipment comes from one MPS ship, capable of providing 2,700 Marines with 15 days of sustainment.
- the Low Intensity Conflict MEB [LIC MEB (1)] - all equipment comes from two MPS ships and an afloat MEU of four or five amphibious ships. It is capable of providing 12,500 Marines with 30 days of sustainment.
- the LIC MEB (2) - from three or four MPS ships (depending on which MPSRON is involved). It is capable of providing 12,500 Marines with 30 days of sustainment.
- the full MEB - the entire MPSRON. It is capable of providing 16,500 Marines with 30 days of sustainment.

B. MPF OPERATIONS

The MPF may be employed in many types of situations, from a humanitarian assistance effort utilizing a MEU Slice to the employment of an entire MEF with all three MPSRON's. Every MPF employment can be broken into four distinct phases: the planning phase, the marshaling phase, the movement phase, and the arrival and assembly phase. The first three phases can occur simultaneously or partially overlap in time; they constitute the most administrative aspects of the operation. Phase IV, the arrival and assembly phase, is the most crucial phase of an MPF operation. During the arrival and assembly, the equipment and supplies flow from the ships to the port and beach, and then from the port and beach to the Marine units inland. The arrival and assembly phase is the area of interest for this thesis.

C. METHODOLOGY

An MPF offload is not a serial process and cannot be easily modeled analytically. Many events occur simultaneously, such as crane operations aboard ship and Logistics Vehicle System (LVS) / Rough Terrain Container Handler (RTCH) operations ashore. Simulation was chosen as the modeling method, using the object oriented simulation language MODSIM II®, in that it easily allows parallel events to occur. Previous simulation models have looked at similar aspects of ship offloading, but for container-only and vehicle-only offloads. Because the MEU Slice offload takes much less time than a multiple ship offload, it is very sensitive to errors in assumptions. Therefore, this model has greater fidelity so that assumptions as to when the LVS's and RTCH's get ashore are unnecessary. Each specific piece of equipment is modeled, not just generic vehicles and containers. When an LVS or RTCH gets ashore in this model, it becomes available to move and load containers.

This simulation was written using the Simulated Mobility Modeling and Analysis Toolbox (SMMAT), of which the author was a co-developer. The need for this product was conceived by Professor Mike Bailey and Professor Bill Kemple of the Naval

Postgraduate School in January 1994, to allow students to conduct thesis research on logistics problems on a larger scale than previously possible. SMMAT is a collection of objects and processes designed to facilitate the modeling of materiel movement along a network. The primary components of SMMAT are junctions, transporters, loaders, and cargo. Within SMMAT, cargo is moved between junctions by transporters, and is transferred between junction and transporters with loaders. Delivery can be determined by the route of the transporters, or can be determined strictly on the basis of cargo destination, with SMMAT choosing the transporter based on availability and compatibility with cargo, junction, and loader. Once SMMAT was operational, it was used as the basis for the author's MEU Slice model.

D. DATA ANALYSIS / CONCLUSION

SMMAT proved to be extremely useful as the toolbox on which the author's MEU Slice Model was built. Once completed, it provided the author with a steady base on which to then produce a more specific model. This thesis demonstrated SMMAT's usefulness as a toolbox; with this powerful modeling toolbox now available, future students will now be able to study more difficult problems in much more detail.

The experiment for this thesis, which tested time to completion of the MEU Slice offload, was conducted as a 2×4 full factorial design, with the simulation model being used to generate data for each of the configurations that resulted from four setup options and two reliability levels. Each run produced 30 replications. The data collected was first analyzed with a two-factor Analysis of Variance (ANOVA), followed by graphical analysis and pairwise differences.

From the eight experiments run, it was determined that there was no significant differences between the setup options or reliability levels, or any significant interaction between the two. Future study is recommended as this is not what the author was anticipating. Additional analysis should include increasing fidelity between the RTCH's and LVS's, with a comparison against the original results to test for a significant difference.

I. INTRODUCTION

A. MARITIME PREPOSITIONING FORCE (MPF) BACKGROUND

Following the Iranian hostage crisis of 1979, the Department of Defense began exploring the concept of using prepositioned equipment to aid in contingency rapid response. The Marine Corps' answer to this initiative was the formation of the Near-Term Prepositioning Force (NTPF), the precursor of today's MPF. The NTPF, deployed in the Indian Ocean, was made up of seven ships containing equipment for the 7th Marine Expeditionary Brigade (MEB).¹ The NTPF was designed to be a short term solution until the MPF was operational. This could not occur until the thirteen ships of the three Maritime Prepositioning Ship (MPS) Squadrons (MPSRON's) were completed. (CRM 89-339, pp. 3, 4).

These three MPSRON's are afloat independently throughout the world (in the Atlantic Ocean, the Pacific Ocean, and in the Indian Ocean) awaiting the call to marry up with a Marine Air Ground Task Force (MAGTF). This marriage of an MPSRON with the personnel of a MAGTF produces an MPF. The MPF concept follows that of the NTPF, to allow for the rapid deployment of a MEB for crisis prevention and intervention. The MPF's provide the United States with "... a balanced, sustainable, multi-role, middleweight, combined arms crisis response team." (Dalton, Kelso, and Mundy, April 1994, p. 20)

When the MPS's were first loaded (1984 - 1986), all ships were evenly loaded with Maritime Prepositioned equipment and supplies (MPE/S) to reduce the impact of one or more ships being lost or unable to participate in an operation. This spreadloading forced

¹ A MEB is a specific type of Marine Air-Ground Task Force (MAGTF). A MAGTF is formed when headquarters, aviation, ground combat, and ground combat service support personnel are brought together under one command for a specific mission or objective. The three most common MAGTG's are, from largest to smallest, the Marine Expeditionary Force (MEF), the MEB, and the Marine Expeditionary Unit (MEU).

the use of the entire MPSRON or none of it. The MPSRON could not effectively offload just the MPE/S needed to support a smaller MAGTF. In the mid to late 1980's, discussions throughout Headquarters, Marine Corps (HQMC) centered around the possibility of restructuring the MPSRON's. Though the MPF had been extremely successful in past operations, it needed to be made more responsive and flexible for future contingencies (A.M. Gray, Speech, 1 Sept 1989). Due to these discussions, the Commanding Generals, Atlantic and Pacific Fleet Marine Forces (CGFMFLant and CGFMFPac) were tasked to study and develop a suite of varying MPF force modules for use by the Unified Commanders in case of contingencies and crises. Following this initial study, the Center for Naval Analysis (CNA) was asked to refine this concept of force modules. From CNA's study, the present Force Module Concept was born. This concept allows for more flexible MPF employment; each MPSRON can be unloaded in different ways to let it meet any one of the following four distinct threat levels:

- the MEU Slice - all equipment comes from one MPS ship, capable of providing 2,700 Marines with 15 days of sustainment.
- the Low Intensity Conflict MEB [LIC MEB (1)] - all equipment comes from two MPS ships and an afloat MEU of four or five amphibious ships. It is capable of providing 12,500 Marines with 30 days of sustainment.
- the LIC MEB (2) - from three or four MPS ships (depending on which MPSRON is involved). It is capable of providing 12,500 Marines with 30 days of sustainment.
- the full MEB - the entire MPSRON. It is capable of providing 16,500 Marines with 30 days of sustainment. (CNA CNR 190, March 1991, p. 3)

Desert Shield and Desert Storm provided the Marine Corps with the opportunity to reconfigure the MPSRON's with the force modules sooner than expected. When the MPSRON's were regenerated after Desert Storm, the ships could be loaded under with the new force modules in place.²

² Regeneration is the methodical approach to restore the MPSRON to its original strength and to attain full operational capability. In this case, it involved restructuring the types and quantities of MPE/S aboard the individual ships.

B. PROBLEM

During the Cold War, all MPF operational and logistical planning was completed assuming full employment of the force. In the Post Cold War era, using the force modules, it is no longer guaranteed that an MPF will be deployed in full. The MPF has "a capability of individual ship, squadron, or force employment to deliver on-scene humanitarian assistance or a fully combat-ready Marine Expeditionary Force." (Dalton, Kelso, and Mundy, April 1994, p. 20) A very likely scenario is the deployment of the MEU Slice, the smallest of the four levels, in a humanitarian assistance effort. This would be similar to OPERATION RESTORE HOPE, the humanitarian relief of Somalia, but on a smaller scale. Present MPF doctrine calls for the rapid deployment of a MAGTF and MPSRON to a secure environment where the offload and marrying up can occur (FMFM 1-5, p. 1-1). In the humanitarian assistance scenario, the offload environment may not be quite as secure as hoped. The total offload and throughput time becomes critical since the Marines supporting the operation are extremely vulnerable until their marriage with the MPE/S is complete.

In the worst case, the MEU Slice would have to be offloaded with MEU Slice equipment only. This would occur if no port facility was available; the offload would then proceed instream vice pierside.³ But, the MEU Slice includes only limited material handling equipment (three Rough Terrain Container Handlers [RTCH's]) and transportation assets (seven Logistic Vehicle Systems [LVS's]), so the allocation of these resources is believed critical to minimizing the throughput time. Also, since the force modules are relatively untried, the best setup of the Arival and Assembly Area (AAA) for a MEU Slice offload supporting a humanitarian assistance effort is not known.⁴ This thesis

³ An instream offload occurs when the ship anchors offshore and lighterages transport the equipment and supplies ashore.

⁴ The best setup is the one that allows for the quickest marriage of Marines and equipment.

will look at four possible setups of the AAA and determine which provides for the quickest offload and throughput.

The setup of the AAA is determined by the RTCH allocation. Each Container Operations Terminal (COT), designed to receive all containers for the associated Major Subordinate Element (MSE), will require at least one RTCH.⁵ The following describes the four candidate organizational options within the AAA for the setup of the COT's.

- One COT, using two RTCH's at the beach and one RTCH at the COT.
- One COT, using one RTCH at the beach and two RTCH's at the COT.
- Two COT's, using one RTCH at the beach and one RTCH at each COT. The first COT will receive containers for the CE and the GCE; the second COT, for the CSSE and the ACE.
- Two COT's, using one RTCH at the beach and one RTCH at each COT. The first COT will receive containers for the CE, the GCE, and the CSSE; the second COT, for the ACE.

The setup which gives the quickest offload and throughput is not necessarily the setup that the MAGTF Commander should choose. The quickest setup may not be the most tactically sound. This model will provide him with one extra piece of information with which this decision can be made.

⁵ The MSE's are the Command Element (CE), the Ground Combat Element (GCE), the Combat Service Support Element (CSSE), and the Aviation Combat Element (ACE).

II. MPF OPERATIONS

A. MPF OVERVIEW

The MPF may be employed in many types of situations, from a humanitarian assistance effort utilizing a MEU Slice to the employment of an entire MEF with all three MPSRON's. Every MPF employment can be broken into four distinct phases: the planning phase, the marshalling phase, the movement phase, and the arrival and assembly phase (OH 1-5-1, pp. 1-5, 1-6). The first three phases can occur simultaneously or partially overlap in time. In addition, they constitute the most administrative aspects of the operation. Phase IV, the arrival and assembly phase, is the "final and most crucial phase of an MPF operation." (FMFM 1-5, p. 8-1) The first three phases are controlled by both the MAGTF Commander and the Commander, MPF (CMPF). The MAGTF Commander controls the ground and air side of planning, marshaling, and movement while the CMPF controls the sea aspects. They must also coordinate so that all issues are covered. The arrival and assembly phase is where most of the interaction takes place. The CMPF controls the flow of equipment and supplies from the ships to the port and beach, while the MAGTF Commander controls the flow from the port and beach through the AAA. The arrival and assembly phase is the area of interest for this thesis. Before the specifics of the arrival and assembly are discussed, a general understanding of the entire MPF operation is necessary.

1. The Phases of Operation

a. *Planning Phase*

The planning phase starts with the issuance of a warning order and continues throughout the entire operation (FMFM 1-5, p. 2-8). This phase encompasses both contingency and execution planning. Contingency planning takes place when only a hypothetical situation is known while execution planning occurs when the commitment of

a force is imminent. (FMFM 1-5, pp. 3-1, 3-2). The concepts for marshaling, movement, and arrival and assembly are developed during this phase. The MAGTF Commander and the CMPF must work together in this phase.

b. Marshaling Phase

The marshaling phase begins with the first Marines and Sailors arrive at a marshaling area and is complete when the final aircraft leaves the departure airfield. (FMFM 1-5, p. 2-10) The movement of Marines and equipment from their home base to the marshaling area falls within this phase. This is controlled by the MAGTF Commander.

c. Movement Phase

The movement phase begins when the first Marines or ships begin transiting toward the Area of Operations and ends with the last Marine or ship entering the AAA (FMFM 1-5, p. 2-12). During this phase, the Force is separated into elements that will deploy by air, the Fly in Echelon (FIE), and the elements that will deploy by sea, the MPSRON and associated support ships. The MAGTF Commander controls the FIE while the CMPF controls the movement by sea. A detailed breakdown of the FIE will appear later.

d. Arrival and Assembly Phase

The arrival and assembly phase begins with the arrival of the first Marine of the Main Body or ship of the MPSRON at the AAA and is complete when the MAGTF is combat capable. The CMPF decides when termination of the MPF operation is necessary, based on the recommendation of the MAGTF Commander. It is not necessarily when the final supply or piece of equipment is married with its designated unit. This phase includes the reception of all Marines and equipment and the distribution of equipment and supplies to the Marines (FMFM 1-5, p. 2-14). The MAGTF Commander controls operations ashore while the CMPF controls operations at sea. The MAGTF forms separate arrival and assembly organizations to execute the timely and thorough throughput of equipment and supplies.

2. The Fly-In-Echelon (FIE)

a. Survey, Liaison, and Reconnaissance Party (SLRP)

The purpose of the SLP is to assess conditions, conduct initial reconnaissance, and make liaison with local authorities, if appropriate, and to report the findings to MAGTF Commander. Ideally it will deploy five to seven days prior to the MPSRON. (MPF Staff Planning Course [SPC], p. HO-315-1-2)

b. Offload Preparation Party (OPP)

The OPP is a temporary element comprised of maintenance personnel, embarkation personnel, and equipment operators; its purpose is to help the ships' crews prepare offload systems and equipment for debarkation once they arrive in port. The OPP ideally will meet the MPSRON no later than four days before it arrives at the AAA. The OPP will dis-establish on arrival at the AAA, and its members will become the skeleton of the debark crew. (MPF SPC, pp. HO-314-1-2 - HO-314-1-4)

c. Advance Party

The Advance Party is the next element of the FIE to arrive at the AAA; it is made up of representatives from all MSE's. They link up with the SLP to organize offload control agencies and to ready the AAA for the Main Body arrival. They also augment the OPP to form the remainder of the debarkation crew.

d. Main Body

The Main Body is comprised of the rest of the FIE Marines not mentioned in one of the previous elements. It also includes equipment necessary for the operation. For a full MEB offload, it should not exceed 250 sorties aboard Air Force transports. The Main Body arrival at the AAA must be coordinated in such a way as to mirror the offload of the ships.

e. Flight Ferry

The Flight Ferry involves the aircraft from the ACE that can self-deploy to the AAA with support of aerial refueling (FMFM 1-5, p. 7-4).

3. Arrival and Assembly Organizations

a. Arrival and Assembly Operations Group (AAOG)

The AAOG, whose nucleus is from the SLRP, is comprised of personnel from all MSE's of the MAGTF, and it is responsible for coordination of the arrival and assembly operations. This includes both the flow of personnel and equipment from the arrival airfield to the AAA and the flow of equipment and supplies from the port and beach to the MSE's. They work closely with the NSE's Primary Control Officer (PCO), who controls the flow of equipment and supplies from the MPSRON to the port and beach.

b. Landing Force Support Party (LFSP)

The LFSP is an element of the CSSE and is responsible to the AAOG for the throughput of personnel, equipment, and supplies at the arrival airfield, beach, and port. The LFSP is made up of the following elements.

(1) Beach Operations Group (BOG). During an instream offload, the BOG must work closely with the NSE's Beach Party Group, who controls the landing of lighterages at the beach.

(2) Port Operations Group (POG). During a pierside offload, the POG must work directly with the ship's debarkation officer to ensure the timely offload of each ship.

(3) Arrival Airfield Control Group (AACG). The AACG must coordinate with the Air Force to ensure the timely arrival of personnel and equipment.

c. Arrival and Assembly Operations Elements (AAOE's)

An AAOE is formed for each MSE, and its purpose is to receive equipment and supplies from the LFSP, depreserve and perform maintenance when necessary, and pass on usable equipment and supplies to the using units.

B. THE MEU SLICE

1. Overview

The differences between a normal MPF operation and a MEU Slice specific operation occur during the arrival and assembly phase. The planning, marshaling, and movement phases are extremely similar independent of which module is being implemented. When a MEU Slice is employed, it involves only one ship from the MPSRON, normally the flagship. A secondary ship is designated backup and will be ready if the flagship is not available. The MEU Slice ship is loaded so that the necessary MPE/S can be offloaded with the minimal offload of other MPE/S. The equipment required for the MEU Slice is approximately 120 vehicles, as opposed to the entire load of 384 vehicles. It requires approximately 150 containers, as compared with the entire MPSRON's approximately 2,000 containers. (CRM 91-38, pp. D-6, E-2)

2. Arrival and Assembly

This is the phase where the full MEB MPF Operation and the MEU Slice MPF Operation differ mostly. For the full MEB Operation, the full MPSRON would be offloaded in a benign port with much of the material handling equipment provided by the Host Nation. The offload would most likely be pierside, with the added possibility of some MPE/S offloaded instream. For a MEU Slice offload, only part of one ship, normally the MPSRON flagship, will be offloaded. Additionally, Host Nation support can not be expected, so the entire offload must be accomplished using organic assets only. Organic assets include the ship's material handling equipment as well as the MEU Slice equipment. Additionally, as mentioned previously, the offload of a full MEB MPF will occur, by

doctrine, in a secure port. Experience has shown, as with OPERATION RESTORE HOPE in Somalia, that the port chosen for offload and throughput may not be totally secure. The MEU Slice offload and throughput will more likely be similar to OPERATION RESTORE HOPE than the totally secure port of OPERATION DESERT SHIELD that doctrine stipulates.

III. METHODOLOGY

A. SIMULATION

An MPF offload is not a serial process and cannot be easily modeled analytically. Many events occur simultaneously, such as crane operations aboard ship and LVS / RTCH operations ashore. Simulation was chosen as the modeling method, using the object oriented simulation language MODSIM II, in that it easily allows parallel events to occur.

Previous simulation models have looked at similar aspects of ship offloading. For example, one previous NPS thesis (Sumner, 1991) modeled container offload while another (Noel, 1993) considered only vehicles. While these theses were also concerned with total offload time, they were not strictly dependent on the organic offload assets. Noel's model did not consider containers, so the availability of RTCH's and LVS's was irrelevant, and Sumner's model examined a larger offload of two ships instream. Because the MEU Slice offload takes much less time than a multiple ship offload, it is much more sensitive to errors in assumptions. Therefore, this model has greater fidelity so that assumptions as to when the LVS's and RTCH's get ashore are unnecessary. Each specific piece of equipment is modeled, not just generic vehicles and containers. When an LVS or RTCH get ashore in this model, they become available to move and load containers.

In addition, to eliminate the requirement to develop a new model to study each aspect of MPF operations (or other similar transportation and mobility problems), the author, and others, developed a general transportation and logistics mobility modeling and analysis toolbox (discussed below) and the author developed a MEU Slice offload model as an extension to it. This extension provides the building blocks for unlimited future MPF modeling.

B. SMMAT - THE TOOLBOX

1. Description

The Simulated Mobility Modeling and Analysis Toolbox (SMMAT) is a collection of objects and processes designed to facilitate the modeling of a transportation and distribution network. Designed originally to handle problems as diverse as battle group vertical replenishment, maritime prepositioned ship offload, amphibious (LCAC) offload, and strategic sealift, it has the flexibility to handle large or small scale problems. The primary components of SMMAT are junctions, transporters, loaders, and cargo, and the functions provided to allow them to interact. Within SMMAT, cargo is moved between junctions by transporters, and is transferred between junction and transporters with loaders. Delivery can be determined by the route of the transporters, or can be determined strictly on the basis of cargo destination, with SMMAT choosing the transporter based on availability and compatibility with cargo, junction, and loader.

Additionally, all junctions have the ability to act as transporters and all transporters can act as junctions. This allows a transporter to receive and deliver cargo as it is transiting. For example, a ship transiting the ocean in a carrier battle group can resupply with helicopters from the supply ship. The ship is a transporter from port to port, but it is also a junction of the helicopter. This ability is accomplished through inheritance. In MODSIM II, when an object inherits another object, it receives all the capabilities of the inherited object. Specifically for SMMAT, junctions inherit transporters, so the junction receives all the capabilities of the transporter, plus the additional capabilities added for itself. Within SMMAT, all transporters are actually junctions functioning as transporters. This allows junctions to move from junction to junction with the ability to have other junctions moving between them.

SMMAT provides several convenient ways to introduce variability into each problem, both during the creation of the scenario, and during the simulation itself. During the creation of the scenario, the number of pieces of cargo at each junction can be varied according to any number of statistical distributions. Additionally, any appropriate characteristic of the cargo (e.g., weight, size, volume, height) can be varied for each

individual piece using the same distributions. During the execution of the simulation, additional variability is possible by using distributions for load times for each piece of cargo, as well as by introducing reliability into the loaders and transporters, allowing them to break at random and be out of action for a variable repair time.

SMMAT also provides the capability to run replications of the scenario as specified by the user, collecting statistics on any parameter the user is interested in measuring. Upon completion of the replications, SMMAT also provides tools for statistical analysis of the total results.

2. Development

The need for a product like SMMAT was conceived by Professor Mike Bailey and Professor Bill Kemple of the Naval Postgraduate School in January 1994, in order to provide a product that would allow students to conduct thesis research on logistics problems on a larger scale than previously possible. SMMAT was developed under their guidance over a nine month period by LT Tim Wilson, USN, LT Ed Kearns, USN, LT Bill Roberts, USN, and the author. SMMAT was developed using MODSIM II® (CACI Products, 1993) on the UNIX workstations.

The development process followed a strict protocol prescribed by Prof. Bailey. First, each component had to meet the common requirements of the diverse applications being modeled by the developers. Additionally, each object and process was thoroughly tested prior to integration into the toolbox.

In order to create a framework allowing the creation of vastly different objects, a common data file structure was used, with special data handlers tailored to put the information contained in the data files into the proper fields of the object being created. Once a basic object has been instantiated; it inherits other attributes as is applicable to turn it into a final object capable of performing the required functions independently.

Interest in SMMAT resulted in an invitation to present at the 1994 CACI SummerSim Simulation Conference in Washington, D.C. in August, 1994, in which Professor Bailey and the four developers attended.

C. THE SCENARIO

For this simulation, a scenario was chosen in which a MEU Slice of the MPF would offload in support of a humanitarian assistance mission. A MAERSK class ship would offload instream and anchor approximately five miles from the beach. The setup ashore would vary as described in the Chapter I. Each COT ashore would be about five miles inland from the beach. The determination of which elements unload at each COT is a function of the setup options. All setup options are the same from the ship to the beach, with the differences becoming evident once ashore. The four options, as described earlier, are

- Option 1 - 1 COT with 2 RTCH's at the Beach.
- Option 2 - 1 COT with 2 RTCH's at the COT.
- Option 3 - 2 COT's with 1 RTCH at each COT and one at the Beach; the CE and GCE unload at COT1 and the CSSE and the ACE unload at COT2.
- Option 4 - 2 COT's with 1 RTCH at each COT and one at the Beach; the CE, GCE, and the CSSE unload at COT1 and the ACE unloads at COT2.

Specifics such as quantities, capacities, and sizes of transporters, loaders, and cargo will be discussed in detail in the following section.

D. THE MODEL FORMULATION

1. Junctions

Junctions are the center building blocks of SMMAT. The junctions contain other objects and allow them to interact. Each junction may contain numerous loading and unloading spots as well as lists of transporters, loaders, and cargo. The main mission of the junction is to control the flow of the transporters docked at it. Once the junction docks the transporter, it tells the transporter to unload, load, and depart.

a. Ships

One ship, from the MAERSK Class, forms the initial junction within this model. The ship has three unloading spots, one for each crane.

b. Beach Areas

The beach areas form the middle junction within this model. This is where control shifts from the Navy to the Marine Corps. Within this model, the beach will be modeled as one junction with one unloading spot.

c. Container Operations Terminals (COT's)

A COT is where all of the containers may be stored; within each COT, the containers are stored by MSE. Each COT will be modeled as an individual junction with one or two offload spots per COT, depending on the option being modeled.

2. Transporters

The transporters perform the bulk of the work once they are accepted by the junction. The transporter controls docking, unloading, loading, departing the junction, and transiting to the next junction. The next destination may be determined by either the transporter itself or the cargo it has loaded. Each transporter has a list of legal destinations to prevent the cargo from taking it to an illegal junction. This prevents, for example, lighterages from the sea from delivering cargo inland from the beach. Each transporter has a list of cargo that makes up that load as well as a field for average speed used to determine transit time.

a. Lighterages

The lighterages used in this model are organic to the one ship that is being offloaded. They will transport the cargo from the ship to the beach. The ship has eight causeways, three causeway sections, powered (CSP's) and five causeway sections, nonpowered (CSNP's). The causeways can be connected in various ways depending on loads to be carried, but every lighter must contain at least one CSP. The number of CSNP's is not limited. A combination of one CSP and two CSNP's would be called a 2+1

lighter, the "2" signifying the two CSNP's and the "1" signifying one CSP . For this model, the ships eight causeways will be formed into two 2+1 lighterages and one 1+1 lighterage. This configuration was chosen due to previous studies, which have found that making all causeway combinations as alike as possible reduces offload time (CRM 89-339, p. 40).

b. Logistics Vehicle Systems (LVS's)

The LVS's will initially be cargo until they arrive at the beach; once there they become transporters. The LVS's will transport the cargo from the beach to the COT's. With only seven LVS's being offloaded within this model, this is expected to cause chokepoints within the offload.

3. Loaders

The loaders are responsible for moving the cargo from the junction to the transporter. Each junction has a list of loader types and gives out loaders as the transporters ask for them. No cargo can be unloaded or loaded without first having a dedicated loader. Each type of loader has specific characteristics that make it unique, such as maximum load and average cycle time. In addition, each transporter and piece of cargo have lists of allowable loader types. These lists prevent, for example, forklifts from trying to load trucks and tanks onto lighterages.

a. Ship's Cranes

Since this model is of an instream offload, the ship's cranes will move all of the cargo from the ship to the lighterages. Each crane on the ship has a capacity of 30 Tons, which never was a factor in this model because it exceeded any cargo offloaded.

b. Rough Terrain Container Handlers (RTCH's)

The RTCH's will initially act as cargo until they reach the beach or specified COT, then they will be able to act as loaders. The RTCH's will move cargo from the lighterages to the beach, from the lighterages directly to awaiting LVS's, from the beach to the LVS's, and from the LVS's to the COT's. Since only the three RTCH's being

offloaded will be used, this is also expected to be a chokepoint and area of concern. The RTCH allocation is the driving force between the different setup options.

4. Cargo

The cargo is what drives the entire model, yet it is the simplest of all modules. When all of the containers have been delivered to the COT's, the simulation is complete. All cargo determined to be necessary for the MEU is initially loaded onto the ship before the simulation begins. To model the conflict between vehicles and containers for lighterage space, all vehicles and containers are delivered from the ship to the beach. Once at the beach, the delivery of containers to the COT's is considered independent of, and more time critical than, the delivery of the vehicles to the AAOE's. Therefore, the delivery of vehicles to the AAOE's is assumed to be not necessary and is not modeled in this simulation. Once the vehicles arrive at the beach, they are removed from the beach's cargo list and are not considered for delivery inland.

The cargo is being brought into the model with the help of the Computer Aided Embarkation Management System (CAEMS), a sub-system of MAGTF II Logistics Automated Information System (LOG AIS). The notional cargo list, with offload priorities and cargo characteristics, used in this thesis was determined from the analysis of the *1st Lt Jack Lummus* load plans (a MAERSK-Class ship from MPSRON-3), and from the recommended changes provided in CMR 91-38, *Reconfiguration of MPSRon-3 To Support The Priority Force Modules*. See Appendix A, the listing of the data files used in the simulation, for the detailed cargo data used; it is provided in the files *simstart.dat* and *cargo.dat*.

5. Randomness

Randomness enters into simulations when the attempt is made to model the real world. In this model, all processes that could be realistically modeled with distributions were so modeled, others were modeled deterministically with the best data available.

a. Loading, Unloading, and Transit Times for the lighterages

The Center for Naval Analyses (CNA) has analyzed MPF operations extensively from the beginning. They have determined through analysis of previous operational results, that the loading, unloading, and transiting of lighterages follow lognormal distribution with varying parameters, dependent upon ship class and distances from the beach (CRM 91-3, p. 26). For this model, the distributions provided for the loading and unloading of the lighterages were used, with slight modifications, but the transit distribution was not. The only drawback to using the distributions for loading and unloading is that they aggregate the individual cargo into one large piece of cargo per lighterage. The entire lighterage cargo list is loaded or unloaded at the exact same time. This is not to the level of detail initially planned for this model. This proved to not be a problem for the loading of the lighterages at the ship, because the lighterage could not leave the ship until it is full anyway. No realism is lost by aggregating at this point.

Realism would be lost, however, by offloading at the beach in aggregate. If aggregation was used, numerous pieces of cargo would arrive at the beach simultaneously for dispersion rather than serially as each lighterage offloaded. It was decided that a separate unload time for each piece of cargo was needed. In order to have the lighterage offload times follow the lognormal distribution provided, and still unload each of n pieces of cargo in a distinct, random length of time, random offload times were generated as follows:

First, a total lighterage offload time, X , was generated from the lognormal distribution.

Next, n $U[0, 1]$ random variables, U_1, U_2, \dots, U_n , were generated. These were rescaled to form Z_1, Z_2, \dots, Z_n by letting

$$U = \sum_{i=1}^n U_i \text{ and } Z_i = \frac{U_i}{U} \text{ so } \sum_{i=1}^n Z_i = 1.$$

Finally, the individual offload times were formed as

$$X_i = Z_i \times X,$$

so

$$\sum_{i=1}^n X_i = X.$$

Once the offload time of each individual piece of cargo was found, these new times were used to determine when each individual piece of cargo was offloaded. This allowed the RTCH access to the cargo sooner than would otherwise have been possible, and added a measure of increased realism to the model.

The parameters of the lognormal distribution for transit time were based upon the specific exercise being modeled. The scenario used in this model was not close enough to any of the observed exercises for the author to comfortably use the associated distributions. It was determined that it would be better to model the transit time deterministically, with different parameters for full and empty loads.

b. Loading, Unloading, and Transit Times for the LVS's

The loading, unloading, and transiting times of the LVS's were not as easily accessible as the lighterage data.

The loading and unloading of the LVS's were determined by the author to be factors of the RTCH, and not of the LVS itself. These were both modeled with the same distribution, $U \sim \text{Uniform}[4, 12]$, where the parameters are in minutes. This distribution is based on the authors experience and on Sumner's thesis (1991), and it seems to satisfy common sense. Firstly, one would expect the loading of the LVS to take a minimum amount of time, no matter where the container is located in the staging area. Secondly, one would expect that the loading would take no longer than a certain time, no matter where the container was located in the staging area. Thirdly, one would expect the containers to be uniformly distributed throughout the staging area. Therefore, a uniform distribution is called for. One could possibly dispute the parameters, but by no more than a minute or so either way, and the author does not feel that this would alter the simulation results significantly.

Since no recently published data was available for the transiting of LVS's, it was modeled deterministically with the same parameter for full and empty loads.

c. Failure and Repair Times

It is necessary to model failure and repair times because they occur in the real world. Not modeling them will most likely give overly optimistic results from the simulation. For the simulation to reveal meaningful results, the reliability input into the model needs to be accurate. Determining the reliability for the different parts of this simulation was difficult. Since most models of MPF operations have stopped at the beach, the author could not find trustworthy reliability data for the LVS and the RTCH from MPF operations, the reliability data used would have to come from a different source.

The Marine Corps keeps detailed maintenance records of all its equipment, but it does not provide accurate reliability data. Even though fields exist on the Equipment Record Orders (ERO's) for mileage, hours, or rounds at the time of breakdown, no requirement exists that this field be filled in accurately. Therefore, it normally is filled with "dummy" numbers, such as 00000 or 99999. Trying to use this information would yield nonsense at best.

The next best solution for reliability information for the LVS and RTCH was to use the results from the systems' operational test (OT) performed before procurement of the items. These numbers show how well the systems performed under various conditions and levels of duress. The disadvantages of this solution are twofold: (1) very few samples were used for the initial OT's and (2) this reliability represents a new system, not a system that has been in operation for a number of miles or hours.

Another possibility is to use availability data from OPERATION DESERT STORM. The advantages of using this data is that it represents units that were deployed in an actual operation. Additionally, the data is available for all the units that took part in Desert Storm, a very large sample to get data from. The disadvantages are that this information is provided in availability form only and it does not represent equipment that has been in storage, as the MPF equipment has been. Even with these disadvantages, it was determined that this information was the best available. In order to

use this availability data, assumptions about Mean Time to Repair (MTTR) would have to be made.

The worst LVS availability in OPERATION DESERT STORM was 93% while the worst RTCH availability was 64% (CRM 91-206, pp. 8, 18, and 36). Using the basic Availability formula of

$$A = \frac{MTBF}{MTBF + MTTR},$$

the MTBF of the LVS is 13.29 times its MTTR and the MTBF of the RTCH is 1.78 times its MTTR. The RTCH availability from OPERATION DESERT STORM is not consistent with previous studies, so RTCH reliability was not treated within this thesis (Sumner, p. 39, 1991). This decision will most likely give optimistic results, but should still allow for the accurate comparison of times among different options. One day was estimated by the author as the MTTR for the RTCH. Both 93% and 100% availability were looked at within the model; 100% was used as a baseline with 93% being a lower bound as to what to expect. Both MTTR and MTBF were modeled using the exponential distribution with 1 day as the parameter for MTTR and 13.29 days as the parameter for MTBF.

6. Data instantiation

The tools used to instantiate the initial data within this model are part of SMMAT. Six data files are necessary for this toolbox to work. One file is written for the junctions, *junct.dat*, one for the transporters, *trans.dat*, one for the cargo, *cargo.dat*, and one for the loaders, *load.dat*. These files contain the static information about each module. Additionally, another file, *simstart.dat*, is written that explains the dynamic relationships of the modules. It lists each junction with its associated lists of transporters, cargo, and loaders. The final data file needed is a list of primary junctions, *pjname.dat*. A primary junction is a junction which does not belong to a larger junction. In the case of this model, the primary junctions are the ship, the beach, and the COT's. These primary junctions are listed in both the primary junction file and in the junction data file. The Lighterages and LVS's are listed in the transporter data file, the cranes and RTCH's are listed in the loader data file, and all of the cargo in its detail is listed in the cargo.dat file. The dynamic data

file includes the ship with its associated transporters, cargo, and loaders. See Appendix A to view the actual files used for this model.

IV. DATA COLLECTION AND ANALYSIS

A. BACKGROUND

The experiment for this thesis was conducted as a 2×4 full factorial design. Thus, the simulation model was used to generate data for each of the eight configurations that resulted from four setup options and two reliability levels. Each run produced 30 replications. The data collected from these runs is included in Appendix B. Table 1 is a listing of the mean values from the eight design settings, along with the column means, row means, and the grand mean.

TABLE 1. SETUP OPTIONS / RELIABILITY MEAN VALUES

	Option 1	Option 2	Option 3	Option 4	Row Means
100 % Rel	5,125.32	5,117.36	5,151.04	5,154.11	5,139.96
93 % Rel	5,155.37	5,159.8	5,224.23	5,109.7	5,162.28
Column Means	5,140.34	5,138.58	5,187.64	5,131.91	5149.62

The data will first be analyzed with a two-factor Analysis of Variance (ANOVA). If factor effects are found to be significant, further study will be done to identify those differences. If no significant factor effects can be found, further analysis will be conducted to look for trends that may indicate possible effects or areas for further study.

B. RELIABILITY LEVEL / SETUP OPTION ANALYSIS

1. Analysis of Variance (ANOVA)

ANOVA was used as to test the significance of reliability level and setup option. A two-way ANOVA was conducted with the reliability at two levels, 100% and 93%, the setup options at four levels, one for each candidate setup previously mentioned,

and each cell containing 30 values, one per replication. ANOVA is an especially useful technique that attempts to attribute the variance in the observations by the level of the factors. A basic assumption in order to use ANOVA is that each observation can be expressed as

$$X_{ijk} = \mu + R_i + SO_j + I_{ij} + \varepsilon_{ijk},$$

for $i = 1, 2; j = 1, 2, 3, 4;$ and $k = 1, 2, \dots, 30.$

X_{ijk} is the k^{th} observation in cell $ij,$

μ is the overall mean,

R_i is the effect due to Reliability,

SO_j is the effect due to the Setup Option,

I_{ij} is the effect due to the interaction of R_i and $SO_j,$ and

ε_{ijk} is the random error of the k^{th} observation in cell $ij.$

ε_{ijk} is normally distributed with mean equal 0 and variance equal $\sigma^2.$ Additionally, it is usually assumed that

$$\sum_{i=1}^2 R_i = 0, \sum_{j=1}^4 SO_j = 0, \sum_{j=1}^4 I_{ij} = 0 \text{ for } i = 1, 2, \text{ and } \sum_{i=1}^2 I_{ij} = 0 \text{ for } j = 1, 2, 3, 4.$$

The hypothesis for the existence of a reliability effect is

$$H_o : R_i = 0 \quad \forall i \text{ (there is no reliability effect)}$$

$$H_a : R_i \neq 0 \text{ for some } i \text{ (there is a reliability effect),}$$

for the setup option effect it is

$$H_o : SO_j = 0 \quad \forall j \text{ (there is no setup option effect)}$$

$$H_a : SO_j \neq 0 \text{ for some } j \text{ (there is a setup option effect),}$$

and for the interaction effect it is

$H_0 : I_{ij} = 0$ " i and j (there is no interaction effect)

$H_a : I_{ij} \neq 0$ for some i and j (there is an interaction effect).

Table 2 contains the results of the ANOVA. When using ANOVA, one should test for the interaction effect first; if the interaction effect is significant, no other tests should be done. Since the F- Statistic of the interaction, 0.2841, is less than the critical $F_{3, \infty 0.1}$, 2.08, the null hypothesis for the interaction cannot be rejected. Infinite denominator degrees of freedom were used for the preceding critical F due to constraints in the F - Table. If a statistic cannot be rejected with infinite degrees of freedom, it will not be rejected for any degree of freedom selected for that parameter. Therefore, no interaction effect exists. Now, testing for reliability and the setup options effects can occur. Since the residual had 232 degrees of freedom, pooling with the interaction to gain fidelity was not necessary. The F- Statistic of the reliability, 0.3226, and the F - Statistic of the setup options, 0.3598, are both less than their respective F critical values, 2.17 and 2.08, so neither null hypothesis can be rejected. It cannot be shown that an effect due to the reliability or setup options exists.

TABLE 2. TWO WAY ANOVA FOR SETUP OPTIONS / RELIABILITY

Source	Degrees of Freedom	Sum of Squares	Mean Square	F - Statistic
Reliability	1	38,429	38,429	0.3226
Setup Options	3	128,562	42,854	0.3598
Interaction	3	101,516	33,839	0.2841
Residual	232	27,635,664	119,119	
TOTAL	239	27,904172		

2. Graphical Analysis

Boxplots provide another method to see if a factor is different from the rest, as well as determining certain attributes about the data. These attributes include the median of the data, the upper and lower interquartiles of the data, the outliers, and symmetry to name a few. The boxplot allows multiple runs to be compared simultaneously, from all

eight, to four when the data is pooled by setup option, to two when the data is pooled by reliability level. (Chambers, and others, 1983, pp. 21-24)

The full boxplot for this experiment, Figure 1, contains eight separate plots, one for each setup option at each reliability level. From this plot, one can see that no significant difference exists between any of the eight samples. The confidence intervals, the inner box within each larger box, overlap so that all eight groups contain similar points. This is another way of showing no difference between groups. Additionally, a few of the groups are slightly skewed, but not so as to provide any useful information about the data.

Figure 1. Boxplot of the Individual Simulation Runs

C. SETUP OPTION ANALYSIS

The setup option graphical analysis was conducted using a pooled boxplot, Figure 2, with four plots. This allows for the comparison of setup options without reliability, assuming reliability is not significant. From the ANOVA, since it cannot be shown that reliability is a significant factor, this was a valid assumption. Nothing on this boxplot seems to be meaningful. As noted above, the confidence intervals all contain similar points

so no significant differences in times can be found. The pooling by setup option did not show any relationships previously hidden by the data.

Figure 2. Boxplot of the Simulation Runs, Pooled by Setup Option

D. RELIABILITY LEVEL ANALYSIS

1. Graphical Analysis

The graphical analysis of the reliability levels was conducted using a pooled boxplot, Figure 3, with two plots. This allows for the comparison of reliability only with setup option assumed to be not significant. As with the previous plot, the ANOVA conducted earlier verifies the assumption that setup option is not significant. Again the confidence intervals overlap so no significant differences can be found between the two reliabilities. This result is somewhat surprising given the MTTR and MTBF used in the model.

Figure 3. Boxplot Results of the Simulation Runs, Pooled by Reliability Level

Using the assumed MTBF of 13.29 days (or 19,137.6 minutes) and the assumed exponential failure and repair times, the probability that a specific LVS survives past the grand mean without failure is approximately equal to

$$P(X > \text{Grand Mean}) = P(X > 5149.62) = (e^{-\frac{5149.62}{19137.60}}) = 0.764.$$

Therefore, the probability that all seven LVS's survive past the grand mean is equal to

$$P(\text{all 7 LVS's survive}) = [P(\text{a specific LVS survives})]^7 = (0.764)^7 = 0.152.$$

Assuming that the operation length is equal to the grand mean mentioned above, 0.152 also equals the probability that all seven LVS's survive an operation. Theoretically, this shows that the simulation runs the same at 100% and 93% reliability only 15.2% of the time. Almost 85% of the time, the simulation at 93% reliability was running with less LVS's than the 100% reliability simulation. Analysis of the simulation output shows the LVS's were indeed breaking down when set at 93% reliability with about one of the seven

reaching its failure time before the simulation ended. One could possibly conclude from these results that the LVS's are not taxed enough in this scenario. The loss of one or two LVS's for a short time does not seem to slow the system down as expected.

2. Differences in the Mean

In addition to the graphical analysis just discussed, the method of pairwise differences can be used to test for significant differences due to reliability. This method is useful because it exploits dependence in the data (e.g. due to setup option effect) to reduce variance, thus gaining precision. See Appendix C for a listing of differences in time by reliability level for each setup option. Assuming the difference are normally distributed, the following hypothesis test can be used:

$$H_0: \mu_{R(100)} - \mu_{R(93)} = \mu_d = 0$$

$$H_a: \mu_{R(100)} - \mu_{R(93)} = \mu_d \neq 0,$$

where

$\mu_{R(100)}$ is the mean value of time at 100% reliability,

$\mu_{R(93)}$ is the mean value of time at 93% reliability, and

μ_d is the difference between them.

The test statistic used for this test is Student's t statistic,

$$t = \frac{\bar{d}}{s_d/\sqrt{n}} ,$$

where the null hypothesis will be rejected if $|t|$ is greater than the critical t from the tables. (Mendenhall, Wackerly, and Scheaffer, 1990, pp. 573-575) For this problem,

\bar{d} , the sample average of the differences, equals -25.26,

s_d , the sample standard deviation of the differences, equals 475.223, and

n , the number of samples, equals 120.

This gives $t = -0.58227$, which results in a two-sided p-value of 0.5687, and leads to a failure to reject the null hypothesis. Therefore, it cannot be shown that a difference exists

between $\mu_{R(100)}$ and $\mu_{R(93)}$. If no difference exists between the means, then it cannot be shown that reliability tested here has an effect on total offload time.

V. CONCLUSIONS AND RECOMMENDATIONS

A. CONCLUSIONS

1. SMMAT

The Simulated Mobility Modeling and Analysis Toolbox (SMMAT) was developed and built by faculty and students of the Naval Postgraduate School, including the author. It is designed to provide students interested in modeling transportation and distribution problems with a basic toolbox of object oriented computer modules on which more specific thesis related simulations could be built.

SMMAT proved to be extremely useful as the toolbox on which the author's MEU Slice Model was built. Once completed, it provided the author with a steady base on which to then produce a more specific model. SMMAT's overall usefulness was not taken advantage of within this thesis. As much as 90% of the time spent writing computer code for this thesis was spent on SMMAT. Future users of SMMAT will not have that burden. They will be able to take SMMAT and use it from the start. With this powerful modeling toolbox now available, they will then be able to study more difficult problems in much more detail.

2. The MEU Slice Model

An MPF employment is a very delicately balanced operation including elements of many organizations. The operation can go awry at any time, from the initial planning phase through the marshaling and movement phases to the arrival and assembly phase. At no time during this extremely busy operation, is it more hectic than during its final phase, the arrival and assembly. It is during this phase that the marriage of Marines and their equipment must occur.

Of all MPF employments, the one most critical to time is the MEU Slice force module. The MEU Slice allows for the offload of a partial ship in order to support a MEU

ashore. For this force module, the equipment and supplies must be ashore as rapidly as possible, but it must be accomplished with only organic lighterages afloat and minimal RTCH's and LVS's ashore.

The most crucial phase, the arrival and assembly, of this most time sensitive force module, was looked at in this thesis. Specifically, the instream offload, was examined as the worst case possible. Different setups ashore were examined in order to determine if these setup options affected the offload and throughput process. Additionally, two levels of LVS reliability were examined to see if that too was a factor.

From the eight experiments run, four setup options at two reliability levels each, using the assumptions and parameters previously listed., it was determined that there were no significant differences between the setup options or reliability levels, or any significant interaction between the two. This is not what the author was anticipating. The model did not bring out the expected difference. There are four possible explanations for this.

- The model is not doing what it is supposed to do.
- The assumptions and parameters are incorrect.
- The model does not have enough fidelity to capture the effects between the RTCH's and the LVS's.
- The author could be wrong.

A detailed analysis of the simulation output has verified that the model does indeed do what it is supposed to do. This eliminates the first alternative from above as a possibility. It is not as straight forward a process to reach a conclusion on the second and third alternatives. After rechecking the assumptions and parameters used within the model, the author has concluded that 100% RTCH reliability may not be a valid assumption. Other assumptions, however, such as lighterage reliability and transit times, do seem valid. Although they play a part in the overall simulation results, they are relatively constant for all setup options, and do not effect which setup option produces the quickest offload.

Another possibility, that not enough fidelity exists within the model, can only be confirmed by actually increasing the fidelity and comparing the results. The fourth alternative, that the author's intuition was incorrect, is a definitely possibility. This can be determined after the first three alternatives are eliminated. The following recommendations for further study are offered so that the final three alternatives can be examined more closely.

B. RECOMMENDATIONS

1. SMMAT

In the process of utilizing SMMAT to develop the MEU Slice Model, a few areas for future refinement were determined. As mentioned earlier, within SMMAT, junctions inherit transporters. Using this same concept, the author recommends the inheritance structure shown in Figure 4.

Figure 4. Recommended SMMAT Inheritance Structure

This structure puts the cargo as the lowest entity within SMMAT. Every loader will inherit cargo, so they have the capability to be carried as well as to carry. All transporters

will inherit loaders, so each transporter has the capability to load and unload itself, as well as to transit. Each junction will continue to inherit a transporter, so it can receive cargo as well as deliver it. Without the use of this structure, the author was forced to create an LVS cargo for the ship and then create a new LVS transporter once the LVS cargo reached the beach, and then dispose of the LVS cargo. This new structure will allow an LVS to be carried on a ship as a piece of cargo and then seamlessly act as a transporter once it hits the beach.

2. The MEU Slice Model

Additional RTCH's could be added to the model and new, untried setups could be modeled. This would be quite beneficial, since there is presently debate within the Marines Corps as to whether there are adequate RTCH's within each MSPRON (Pleis, January 1993, pp. 19 - 21).

Within the MEU Slice model, fidelity could be increased with the results of both models being compared to see if a difference exists. If the new SMMAT structure is adopted, it would be quite easy to model the RTCH as a transporter with loader capabilities. This would give much more fidelity to the beach operations. It would allow the RTCH to transit, and load and unload at junctions. A whole sub-system could be modeled at the beach at a level of fidelity greater than the rest of the model. This would be useful because the beach is where the critical interaction occurs and crucial decisions are made.

RTCH reliability should be taken into account once more reliable figures are determined. Additionally, the following could be included to reduce the assumptions in the model and to add more realism to the scenario.

- RTCH loading and unloading also needs to monitored closely so that they can better be modeled in future simulations. Experience is always useful, but not always available.
- Crane and lighterage reliability; the cranes and lighterages were assumed to never break down, but this was overly optimistic.

- Lastly, LVS transit distributions could add additional realism if accurate distributions could be determined.

The results of this new model should also be compared to the original results to see if a difference exists. If the results, after increased fidelity and fewer assumptions, show a difference between setup options, then the author's intuition was correct. If no difference occurs, then the fourth alternative listed previously must be correct, that the author was wrong in his intuition and there is no difference between setup options.

APPENDIX A - INPUT DATA FILES

PJNAME.DAT

```
